Provenance and review status 22

The standard – the lowest government limit in the world (µg/kg)

One number per analyte, per product form: **the strictest maximum level any government sets, anywhere.** The cow-milk and soy formulations are an internal calculation step, not a published distinction. Where the law splits them (cadmium, nickel), the published limit is the **lower** of the two, so the single category number sits at or below every national law for both formulations and never certifies a product above its own legal ceiling. Aluminium is the one exception — soy formula is inherently aluminium-rich, so it keeps the law's own cow / soy split rather than penalise soy for a trait its regulator already accounts for (see the table note).

Analyte	Powder (as-sold)	Ready-to-feed (as-consumed)
Lead (Pb)	20	10
Inorganic arsenic (iAs)	20	10
Cadmium (Cd)	10	5
Mercury (tHg)	monitored	monitored
Nickel (Ni)	250	100
Aluminium (Al)	3500 cow / 7000 soy	500 cow / 1000 soy
Tin (Sn)	5000	714
Total chromium (Cr)	2000[d]	monitored

monitored = no government sets a formula limit for this analyte (reflex speciation screen applies; see the notes below). [d] *= broad-dairy fallback, no formula-specific limit exists. Tin is the FSSAI (India) as-sold value, confirmed against the 2011 primary text.* ***Aluminium is published as***

***the law's own cow / soy split**: soy formula is inherently aluminium-rich — which is why regulators set the soy limit at 2× cow — so adopting the lower number would penalise soy for a trait its own regulator already accounts for. Every other analyte is a single lowest-worldwide number. The per-country derivation for every number — including the cow/soy split that feeds it — is the matrix that follows.*

How certification works against these limits

Tier 1 metals — lead, inorganic arsenic, cadmium, mercury — are zero-tolerance. A single lot over the limit blocks certification. These are the metals with no safe intake for infants, so the program holds them to the strictest world limit with no transitional allowance.

Tier 2 metals — nickel, aluminium, tin, hexavalent chromium — carry a transitional allowance. A product measuring up to **150 % of the limit** earns transitional certification (Status B) while it remediates, because these metals have established tolerable intakes and their elevations are often supply-chain-driven rather than avoidable at will. Above 150 % is probation; the allowance is transitional, not permanent.

A legal violation always blocks certification, regardless of HMTc status. Because every limit here is a government maximum level, any lot that fails the *program* limit by more than the Tier 2 allowance is at or near a real legal exceedance in the strictest jurisdiction — the certification gate and the regulatory gate move together.

Certification status	Meaning
A — Full	All analytes ≤ 100 % of limit
B — Transitional	A Tier 2 metal between 100–150 % of limit, under a remediation plan
C — Probation	150–200 %, or any Tier 1 exceedance
D — Suspension	> 200 % of limit
E — Revocation	Repeated or unremediated failure

Per-country government limits, by subcategory

CX = Codex · CA = Canada · CN = China · IN = India · BR = Brazil · KR = South Korea · GS = Gulf (GSO) · AN = Australia/NZ · US = US-FDA.

Each cell is that government's infant-formula limit **normalized to the subcategory's basis** so the columns are comparable. [c] = converted across the 1:7 powder↔as-consumed reconstitution boundary (the government's own limit is in the other basis; see the provenance table). Blank = that government sets no formula limit for the analyte. **The HMTc limit is the lowest comparable value in the row.**

Powder · cow-milk (powder, as-sold basis, µg/kg)

Analyte	EU	UK	CX	CA	CN	IN	BR	GS	AN	HMTc limit	Binding source
Lead (Pb)	20	50	70[c]	70[c]	80	200	70[c]	70[c]	70[c]	**20**	EU

Canned soy formula tin (separate product form): EU 50000, UK 50000 µg/kg. [d] *= broad-dairy fallback (no formula-specific limit exists).* [c] *= basis-converted.*

Three cells where the method reaches its limit – stated plainly

The tightest-government method is only as complete as the world's regulators. Three cells cannot be set by lookup, and this standard says so rather than inventing a number:

1. **Mercury (all subcategories) — no government sets an infant-formula limit.** The nearest limit in the world is China's 20 µg/kg for *canned complementary foods*, a different product. There is nothing to adopt. Mercury is therefore **monitored, not limited**: every certification lot is screened for total mercury, with reflex methylmercury speciation on any detection, but no numeric pass/fail limit is published where no government has set one. This is the honest output of the method, not an omission.
2. **Hexavalent chromium — unregulated in food worldwide.** No government sets a Cr-VI food limit (the only Cr-VI limits are for drinking water). Total chromium has one applicable government number — China's 2,000 µg/kg for milk powder (a broad dairy category that covers cow-milk formula powder), shown with a [d] flag as a fallback, not a formula-specific limit. Cr-VI itself is **monitored, not limited**, with a 100 µg/kg total-chromium manufacturing-anomaly screen that triggers speciation.
3. **Tin — regulated, but on an uncertain basis.** Only India sets a non-canned infant-formula tin limit (5,000 µg/kg); every other government regulates tin only for *canned* product (50,000 µg/kg, a container-migration limit). The India value's basis is unresolved in our register (the secondary source records it as-consumed; the FSSAI 2011 primary text records it as-sold — a 7× difference). The tin cell is therefore **provisional** pending confirmation against the

primary Indian instrument; canned formula is held to the 50,000 µg/kg world consensus.

Everything else in this standard is a firm, citable government maximum level.

Provenance and review status

Every value above is drawn from `data/evidence/regulatory_limits.csv` (250-row worldwide regulatory register). China, Brazil, India, US-FDA, and Codex infant-food rows are confirmed against primary government instruments (marked PRIMARY-CONFIRMED in the register, 2026-08-03); the remaining jurisdictions (EU, UK, Australia/NZ, Canada, Gulf, South Korea) are web-verified against the official instrument and pending a primary-text cross-check. The two provisional cells above (India tin basis; the Cr-VI/mercury monitored-not-limited determinations) and the primary-text cross-check on the remaining jurisdictions are the items outstanding before external publication. **This standard is ready for legal-counsel review; it is not yet counsel-cleared.**

The Institute of Contaminant Standards operates the Heavy Metal Tested & Certified program. This is certification-program material, published separately from the Heavy Metal Index literature reference at heavymetalindex.com.
